

FastBoot Detect

The utility, for adding any WinPE to startup , helps to understand at startup whether the "lying" system is in FastBoot mode. With such a system / disk partition, it is better not to perform any actions, because they are not applied and "break" the file system.

At startup, all hard disk partitions are scanned for the presence of the file: hiberfil.sys, after that, the file header is read, if there is a text: HIBR , then the system is in sleep mode. The corresponding letter of the section is displayed in the information window of the utility.

What to do next is up to the user himself. Or reboot the system, or break it down with your actions.
